Abstract: Anemia is an important public health and clinical problem. Observational studies have linked iron deficiency and anemia in children with many poor outcomes, including impaired cognitive development. In this study, we summarize the evidence for the effect of daily iron supplementation on cognitive performance in primary-school-aged children. We searched electronic databases (including MEDLINE and Wangfang database) and other sources (August 2015) for randomized and quasi-randomized controlled trials involving daily iron supplementation on cognitive performance in children aged 5-12 years. We combined the data using random effects meta-analysis. We identified 3219 studies; of these, we evaluated 5 full-text papers including 1825 children. Iron supplementation cannot improve global cognitive scores (Mean difference 1.05, 95% confidence interval [CI] -2.69 to 4.79, P<0.01). Our analysis suggests that iron supplementation improves global cognitive outcomes among primary-school-aged children is still unclear.

Keywords: Iron supplementation, cognitive performance, meta-analysis

Introduction
An estimated 25% of school-aged children worldwide are anemic [1]. Iron deficiency is associated with inadequate dietary iron and, in developing settings, hookworm and schistosomiasis [2]. In developed settings, anemia is prevalent among disadvantaged populations, including newly arrived refugees, indigenous people [3].

In observational studies, iron deficiency has been associated with impaired cognitive [4, 5]. A causal relation between iron deficiency and cognitive impairment has not been confirmed [6]. The effect of longer-term treatment remains unclear. There is an urgent need for further large randomised controlled trials with long-term follow-up.

Optimizing cognitive in primary-school-aged children could have life-long benefits. We performed this meta analysis of the effects of daily iron supplementation, a commonly used strategy to combat anemia in primary-school-aged children. To further confirm that whether daily iron supplementation can improve cognitive impairment.

Methods
Information sources
We searched the following electronic databases: MEDLINE and wanfang database. We reviewed the references of the identified articles and of previous systematic reviews. There was no language restriction applied. We performed the searches on July 4, 2015.

Inclusion criteria
We included randomized controlled trials that included primary-school-aged children (5-12 yr) who were randomly assigned to daily (≥ 5 d/wk) oral iron supplementation or control. We included studies that did not specifically recruit participants from this age range if the mean or median age of participants was between 5 and 12 years. We excluded studies that included only children with a known developmental dis-

ability or a condition that substantially altered iron metabolism, including severe anemia. We included trials involving participants from all countries and socioeconomic backgrounds.

Outcomes

We included the following primary outcomes: cognitive performance (as measured by study authors).

Data extraction

Two authors independently assessed the remaining full-text studies against the inclusion criteria; Discrepancies were resolved through discussion.

Statistical analysis

Meta-analysis was performed for outcomes for which at least 2 studies provided data. We determined the mean difference (MD) for the difference between outcome means or the change from baseline for continuous data measured on the same scale.

We quantified heterogeneity using $I^2$. We considered substantial heterogeneity to exist if $I^2$ was above 50%. We created forest plots to present the effect size and relative weights for each study and the overall calculated effect size. Random-effects meta-analysis was used with calculation of $I^2$.

Result

We combined the data using random effects meta-analysis. We identified 3219 studies; of these, we evaluated 5 full-text papers including 1825 children. Iron supplementation cannot improve global cognitive scores (Mean difference 1.05, 95% confidence interval [CI] 2.69 to 4.79, P<0.01). As showed in Figure 1. No publication bias is found in this meta analysis (Figure 2). Table 1 presents the characteristics of the included studies.

Discussion

Daily supplementation provides the highest dose of iron of any nonparenteral approach and is a commonly recommended clinical and public health strategy for the prevention and treatment of anemia [7]. Our data are chiefly extrapolatable to iron supplementation interventions; alternative approaches to improving iron stores such as food fortification are under evaluation by other systematic reviews [8].

In this review, we found evidence that iron supplementation on cognitive performance among primary-school-aged children is still not sure, including on IQ among children with anemia. Previous systematic reviews have evaluated the efficacy of iron delivered by multiple approaches. A Cochrane review of intermittent iron supplementation in children found insufficient studies reporting cognitive outcomes or adverse effects [9]. Two previous reviews have evaluated the effects of iron on cognitive outcomes among primary-school-aged children. Sachdev and colleagues [10] reported improvements in overall cognitive performance (SMD 0.30) and IQ (SMD 0.41) among children who received parenteral or enteral iron (including fortification). Falkingham and colleagues [11] found no improvement in overall IQ from iron supplementation, but they reported improvements in IQ among participants with anemia (MD 2.5) and improvements in attention and concentration among adults and children older than 6 years of age.

**Limitations**

Our review is limited by significant heterogeneity, which we addressed by use of random effects meta-analysis and predefined subgroup analyses. This heterogeneity appears to be mainly because of differences in baseline anemia status. Unfortunately, several important outcomes (particularly physical performance and growth) were reported by relatively few studies. Further randomized trials evaluating the nonhematologic effects of iron, especially outcomes such as cognitive performance, growth and safety, are needed.

**Conclusion**

In this review, our analysis suggests that iron supplementation improves global cognitive outcomes among primary-school-aged children is still unclear.

**Disclosure of conflict of interest**

None.
