Abstract: Background: Despite the known adverse effects of lambda cyhalothrin insecticide, little is known about its hepatopancreatic intoxication effects. The present study was carried out to elucidate sub-chronic effect of Karat 2.5% EC formulation of lambda cyhalothrin on male albino rats. Methods: To explore the effects of exposure to lambda cyhalothrin on rats and its mechanism, low (1/40 of LD₅₀, 5 mg/kg/day) and high dose (1/4 of LD₅₀, 50 mg/kg/day) lambda cyhalothrin were applied to rats via drinking water for 3 months. Blood samples were collected monthly, and the animals were dissected for liver and pancreas’s examination at the end of the experiment. Lambda cyhalothrin administration was associated with the elevation in lipid peroxidation marker, malondialdehyde (MDA), reduction in SH-protein a major marker for antioxidant, as well as basal paraoxonase (PON) in both treated groups throughout the experimental periods. Results: In addition, significant elevations in liver enzymes alanin amino transferase, (ALT), and aspartate amino transferase (AST), as well as plasma acetylcholinesterase (AChE) and glucose level. While, significant reduction in insulin level through the experimental periods. Results of histopathological and histochemical studies showed that lambda cyhalothrin exposure induces liver and pancreatic tissues damage and depletion in glycogen content was pronounced in liver of both treated groups. Conclusions: In conclusion subchronic intoxication with lambda cyhalothrin formulation induced remarkable changes in the examined parameters.

Keywords: Pyrethroids, oxidative stress, liver enzymes, pancreatic intoxication

Introduction

Environmental factors such as life style, drugs, and pollutants play important role in the progression and/or precipitation of diseases like diabetes, hypertension, obesity, and cardiovascular disorders. Indiscriminate use of pesticides resulted in pollution of water, air, soil, and food. Nowadays, the overall pattern of pesticides use has been changed considerably in comparison with the past while the hazards of using such chemicals have been accentuated by the sharp rise in their use in agriculture, industry, and by householders [1-3]. Pyrethroid insecticides have been used in agricultural and home formulations for more than 30 years and account for approximately one-fourth of the worldwide insecticide market [4]. Pyrethroids may be classified into two large groups [5, 6]; type I pyrethroids (e.g. allethrin, permethrin) lack a cyano moiety. Type II pyrethroids (e.g. deltamethrin, fenvalerate and cyhalothrin) have a cyano group in the α-position. In recent years, the use of synthetic pyrethroids has increased due to their obvious advantages. Lambda-cyhalothrin is one of the newer synthetic pyrethroid insecticides with effective immediate and persistent activity against a large variety of arthropods harmful both to human and animal health and to vegetal production. These types of halogenated and lipophilic compounds are generally recognized as potent neurotoxins, characterized by high insecticidal properties and low mammalian toxicity [7]. Exposure to Lambda-cyhalothrin poses both acute and chronic risks. Acute effects include skin and eye irritation, non-cardiogenic pulmonary edema, cardiovascular toxicity, coma, convulsions.
Hepatopancreatic intoxication of lambda cyhalothrin

and severe muscle fasciculation [8]. Chronic effects in rats include decreased body weights, organ weight changes (liver, kidney, brain, heart and lung), reduced brain size [9], cell damage (neoplastic and histopathological lesions), tumors [10] and endocrine toxicity [11]. The aim of the present study is to evaluate, subchronic effect of karate formulation of lambda cyhalothrin well known insecticide on liver and pancreas of albino rats.

Materials and methods

Animals and insecticide exposure protocol

A total of 24 male Rattus Norvogious rats aged 16-18 weeks and weighing 20±20 gm were used in this study. All procedures involving animals were performed in accordance with the guidelines of the standard procedures laid down by OECD 1981 [12] subchronic oral toxicity rodent 90 days study, the protocol of this study was been approved by department of Mammalian Toxicology, Pesticide Central Laboratory, Agriculture Research Center, Egypt. In the present study, the subchronic effects of lambda cyhalothrin on liver and pancreas of male rats have been determined by exposing the animals to different doses (5 and 50 mg/kg/day) equivalent to 2.5% and 25%, respectively, of its oral LD50, 200 mg/kg (Tomlin, 1994). Rats were given low [5 mg/kg/day, Low dose group (LDG) n=8] and high [50 mg/kg/day, High dose group (HDG), n=8] doses of lambda cyhalothrin in drinking water for 3 months (subchronic effects). Lambda cyhalothrin (Karat 2.5% EC formulation) was purchased from El-Naser Company (El-Naser Co. Ltd, Egypt). Control animals (n=8) were supplemented with free access of drinking water. Blood samples has been collected from the retro-orbital plexus vein according to Schermer [13], on heparinized tubes, after 1st, 2nd and 3rd month of treatment periods. Plasma was separated by centrifugation of the blood samples at 3600 rpm for 15 minutes, and kept at -20°C for subsequent use. At the end of the experiment rats were sacrificed by dislocation before tissue sampling for histopathological and histochemical studies.

Histopathology and histochemical examinations

Liver and pancreas organs were dissected and the tissue samples were waxed in Bouin's solution for 14-18 h, processed in a series of graded ethanol and embedded in paraffin. Paraffin sections were cut with at 5 µm thickness and stained with haematoxylin and eosin for light microscopy examination. Other sections from liver and pancreas were stained with Periodic Acid Schiff (PAS) stain according to Bancroft and Stevens [14]. The sections were viewed and photographed on an Olympus light microscope (Olympus BX51, Tokyo, Japan) with attachment photograph machine (Olympus C-5050, Olympus Optical Co. Ltd., Japan).

Biochemical assay

Three ml from the incubation solution of potassium phosphate buffer (pH 7.9 and 75 mmol/l) and DTNB (0.25 mmol/L) was added to 10 µL of plasma samples. Acetylcholinesterase activity was induced by the addition of 10 µL acetylthiocholine iodide (3 mmol/L) and absorbance at 412 nm was read by spectrophotometer [15]. Whereas, total thiol groups of plasma were evaluated spectrophotometrically at 412 nm using DTNB reagent [16]. Lipid peroxidation of plasma was determined by reaction of TBA with MDA the end product of lipid peroxidation according to Ohkawa et al. [17], the pink color produced by these reactions was measured spectrophotometrically at 532 nm to measure Malondialdehyde (MDA) level. Plasma transaminases (AST and ALT) activities were determined according to Reitman and Frankel [18]. Plasma glucose level was determined using the commercial diagnostic kit of stanbio Co., Spain. Total plasma insulin level was determined using radio immunoassay kit of DPC. Co. American, the Coat-A-Count Insulin procedure is a solid phase radioimmunoassay, where in l125 labeled insulin competes for a fixed time with insulin in plasma or serum sample for sites on insulin specific antibody, counting the tubes on gamma counter then yields a number, which converts by way of calibration curve to a measure of insulin present in plasma samples. Paraoxonase was determined in plasma by the method established by Eckerson et al. [19].

Statistical analysis

Data obtained from the biochemical analysis of different groups are represented in tables as Mean ± Standard error (mean ± SE). The significance difference between groups was calculated by one-way analysis of variance (ANOVA) at P<0.05 using the SPSS-PC computer software package version 10.
Hepatopancreatic intoxication of lambda cyhalothrin

**Results**

**Biochemical results**

As demonstrated in Table 1 an elevation in lipid peroxidation biomarker (MDA) was recorded in each of HD and LD treated groups significant versus control and HD groups, respectively at P<0.05 through time intervals 1 month to 3 months. Regarding to the total plasma thiol protein, a significant reduction in the level of thiol protein was recorded in all intoxicated groups throughout the experimental periods as depicted in Table 1. On the other hands, the present data showed reduction in the activity of plasma paraoxonase (PON) among treated groups all through the experimental periods, significant versus control at P<0.05. It must be noted here that there was a significant elevation in PON activity versus control in LL group at P<0.05 at the 3rd month of treatment. Moreover, Table 2 revealed that intoxication with both doses of karate HD and LD induced gradual elevation in plasma AChE activity through all the experimental periods. Significant elevation was in LD group versus control and HD group at 2nd month was noticed. As regards to the results of the liver biomarker enzymes, alanine aminotransferase (ALT) and aspartate aminotransferase (AST), chronic intoxication with both doses of karate induced gradual increase in each of ALT and AST enzymes, significant versus control and other groups throughout the experimental periods. A gradual elevation in plasma glucose in HD and LD groups level was recorded during the experimental periods, concomitant to these findings, reduction in plasma insulin level in all treated groups versus control group was recorded significant at P<0.05.

**Histopathological results**

**Liver examination:** Control group showed normal liver section showing the central vein

Results were expressed as mean ± SE of 8 rats. a significance difference versus control at P<0.05; b significance difference versus HL at P<0.05; c significance difference versus LL at P<0.05.

Hepatopancreatic intoxication of lambda cyhalothrin

and the cords of hepatocytes are radiating from it. The hepatocytes are polygonal in shape and contain vesicular nuclei and acidophilic cytoplasm, the liver cells cords entrap liver blood sinusoids between them, these sinusoids are lined by sinusoid lining cells (Figure 1A). Group HD showed dilatation and congestion of the central vein, liver architecture is disturbed. Degenerative changes were seen in the hepatocytes in the form of vacuolation of their cytoplasm, absence or faint pyknotic nuclei. Widening of the liver sinusoids with mononuclear cellular infiltration was reported (Figure 1B). Group LD showed slight widening and congestion of the central vein, degenerative changes of the hepatocytes, disturbed liver architecture and widening of the liver sinusoids were noted (Figure 1C).

Pancreas examination: Control group showed the acini of the pancreas with their pyramidal cells and each cell has a round nucleus with the characteristic basal basophilia and apical acidophilia. The acini are divided by thick connective tissue septa into groups. Islets of Langerhans were seen as group of round cells scattered between the pancreatic acini and are rich in blood supply (Figure 2A). Group HD showed disturbed acinar architecture with shrinkage of acini. No defined cell boundaries and absence of nuclei in some cells, few hemorrhagic spots were seen (Figure 2B). Group LD also showed disturbed acini to a lesser extent compared to the high dose. Only few cells showed vacuolation of their cytoplasm and no changes were noticed in the endocrine part of the Pancreas (Figure 2C).

Histochemical results

Liver examination: The control liver stained with PAS showed normal liver architecture and cells with red coloration of the wall of the central vein representing the glycogen in the blood vessel wall and few spots in the liver cells (Figure 3A). PAS stained section showed depletion of the glycogen from the liver cells and vacuolation of their cytoplasm was noticed in HD treated group (Figure 3B). In PAS stained section minimal deposition of glycogen was noticed in the liver cells of LD treated group (Figure 3C).
Figure 2. A. Normal pancreas showing closely packed acini with basal basophilia and apical acidophilia. B. A photomicrograph of section of pancreas of group HL showing increased cellularity of Islets of Langerhans (L). C. Pancreas section of group LL showing No changes from the control. H&E. ×250.

Figure 3. A. Control liver stained PAS with showed normal liver architecture and cells with red coloration of the wall of the central vein representing the glycogen in the blood vessel wall and few spots in the liver cells (arrows). B. PAS stained sections of group HL accumulation of glycogen was noticed in the cytoplasm of the liver cells (G). C. PAS stained section of group LL slight deposition of glycogen (G). ×250.
Pancreas examination: PAS stained sections showed only red coloration around the blood vessels in control group (Figure 4A). On the other hand PAS stain in pancreas of HD treated group showed disturbed acinar architecture with Shrinkage of acini and disturbance in glycogen deposition (Figure 4B). However, reduction in the concentration of pancreatic glycogen was noticed in LD treated group (Figure 4C).

Discussion

Exposure to pesticides may involve large segments of population which include agriculture workers and their families. The general population may expose through home application of pesticides or via residues on food [20, 21]. The present results indicated that subchronic intoxication with karate formulation of lambda cyhalothrin at both doses induced elevation in plasma AChE activity. Both type I pyrethroids and type II have been tested for their neurotoxicity in rat brain synaptosomes. Besides increasing Na⁺ influx into synaptic terminals and creating a depolarized hyperirritable synaptic membrane, they increase the release of neurotransmitter acetylcholine [22]. This may stimulate the activity of plasma AChE as in our findings to do its function in biodegradation of neurotransmitter acetylcholine to cholin and acetic acid. Elevation in oxidative stress biomarkers (MDA) in plasma of treated animals is concomitant with reduction in total thiol protein antioxidant biomarker throughout experimental periods in all treated groups. These findings are coincide with that previously reported [23] significant increase in lipid peroxidation in liver and plasma of rats treated with different doses of deltamethrin for 16 and 30 days. Also, an increase in lipid peroxidation in plasma and tissues after treatment with different doses of cypermethrin was recorded [24]. Lipid peroxidation is a process, which is determined by extent of the peroxide-deforming free radical mechanism on the polyunsaturated fatty acid. On the other hand, bithiol are extraordinary efficient antioxidant protecting the cells against consequences of damage induced by free radicals due to their ability to react with the latter. In antioxidant reactions thiols undergo one- electron oxidation with the formation of thyl radicals [25]. Strong oxidative and nitrosylative stress quickly and efficiently diminishes SH containing protein like glutathione [26] where significant
Hepatopancreatic intoxication of lambda cyhalothrin

decrease in sulphydryl content in blood of animals treated with different doses of lambda cyhalothrin. The extent of liver damage appears to be considerable as evidenced by increase in plasma levels of ALT and AST as shown in our results where elevation in liver marker enzymes were pronounced when animals intoxicated with LD and HD, these results were confirmed by histopathological studies where degeneration in hepatocytes and vacuolation in cytoplasm. In consistent with the present results [27] the treatment with cypermethrin induced elevation in liver enzymes activity which in general related to intensity of cellular damage. The damage occurred probably through oxidative stress mechanism and decrease in the activity of free radical scavengers [28]. Elevation in blood glucose level was recorded all through the experimental periods these results run parallel with that previously reported [29, 30] prolonged administration of cyhalothrin, deltamethrin and cismethrin for rabbits and rats respectively induced significant increase in blood and brain glucose level. Concurrent to the glucose results, hypoinsulinemia was recorded in all treated groups all through the experimental periods accompanied with depletion in glycogen content in liver as shown in pancreas as shown in histochemical examination for liver and pancreas. Disturbed acinar architecture, no defined cell boundaries and absence of nuclei in some cells as well as increased of cellularity was recorded in pancreas tissues. The B cells secrete insulin in response to elevated glucose levels and also respond to other substances such as glucagons and acetylcholine [31]. Oxidative stress and decreased of content of free radical scavengers are probably the consequence of pyrethroids toxicity [23, 28] that may damage cell wall and change the depolarization of cell wall. Depletion of glycogen in the liver cells was noticed in both rats treated with the high dose. Subchronic exposure, which resembles human exposure, may induce diabetes associated with stimulation of hepatic glucose-neogenesis and glycogenolysis in favor of glucose release into the blood [32]. Potential roles for paraoxonase in the detoxification of lipid peroxidation and also as an antioxidant have been suggested [33] Low serum paraoxonase activity may lead to increase in reactive oxygen species, occurrence of oxidative stress and oxidative stress can cause hyperglycemia as mentioned above. The activity of this enzyme has been found to be markedly lower in patients with type I and type II diabetes mellitus than controls [34].

Conclusions

In conclusion chronic intoxication with lambda cyhalothrin induced elevation of plasma AChE and hyperglycemia induced due to oxidative stress that induce disturbance in liver function and pancreatic function.
